05/08/2025

Introduction

In today's polarized political climate, public understanding of core democratic values like tolerance, inclusivity, and equality is often shaped by narratives promoted by political parties. A common misconception is that all democratic countries uphold these values uniformly. However, ideology-driven differences among political parties, especially those with populist leanings, may challenge this assumption. This report seeks to clarify how populism relates to key democratic dimensions such as respect for political opponents, minority rights, and gender equality. Through rigorous statistical analysis of a cross-national dataset, this report provides data-driven insights aimed at helping a community leader educate citizens in rural areas about the diversity and implications of global political ideologies.

This project investigates democratic trends across six countries Australia, China, Germany, India, the United Kingdom, and the United States by analyzing the ideological behavior of political parties over a substantial historical period (1970 to 2020). Using the V-Party dataset from the V-Dem project, the study applies both frequentist and Bayesian statistical techniques to uncover patterns in how political parties promote or hinder democratic norms. The goal is to translate complex statistical findings into accessible insights that support democratic awareness and critical thinking among citizens of all ages.

The key research questions explored are:

1. How does the level of populism influence a party's respect for political opponents across different countries?
2. Is there a significant difference in gender equality ideology among political parties across India, the U.S., and Germany?
3. Do countries with higher support for minority rights also exhibit higher political pluralism?
4. How does anti-elitism relate to people-centrism across countries?

Descriptive Overview

The dataset consists of political party-level observations drawn from the V-Dem V-Party dataset, covering the period from 1970 to 2019 for across 178 countries and filtered out to: Australia, China, Germany, India, the United Kingdom, and the United States. It includes annual ideological ratings for various political parties based on expert surveys. Each observation reflects how a party scored in a given year on several key democratic and ideological dimensions.

The core variables used in this analysis include:

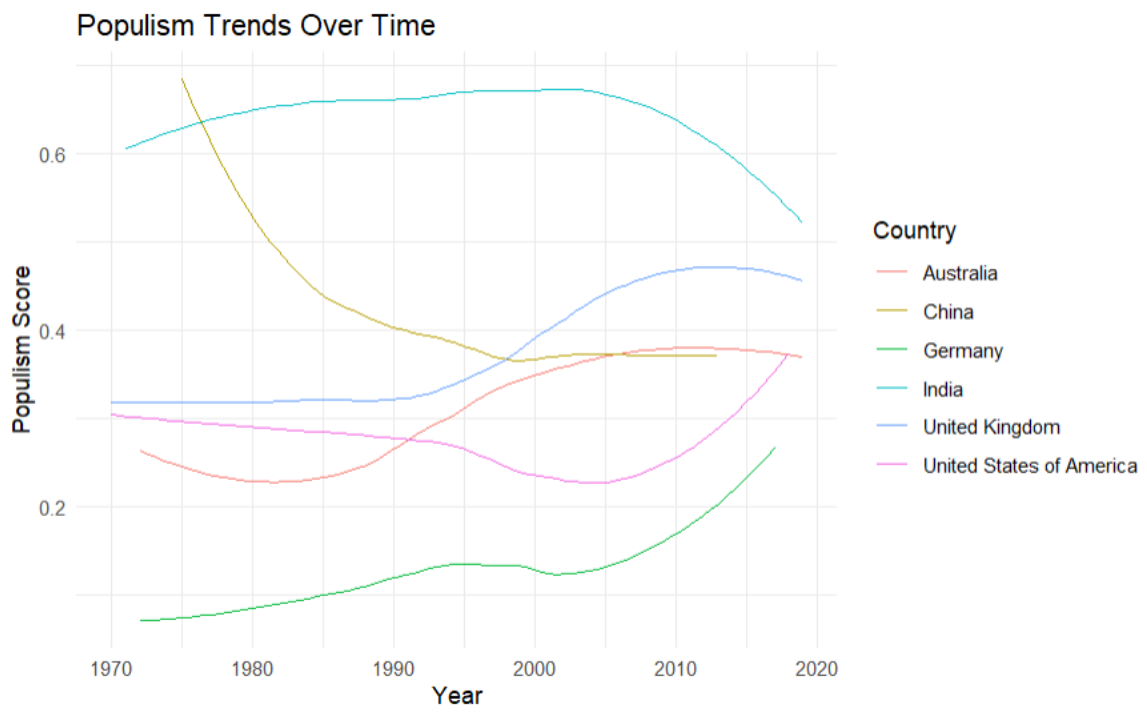
- **populism**: Captures the extent of populist rhetoric, typically involving anti-establishment sentiment and appeal to the "common people."
- **respect_opponents**: Measures the degree of respect a party shows toward its political opponents, indicating democratic tolerance.
- **gender_equality**: Represents party commitment to gender equity in society and politics.
- **minority_rights**: Reflects support for the civil rights and freedoms of minority groups.
- **political_pluralism**: Describes the party's endorsement of the coexistence of multiple political perspectives.
- **anti_elitism**: Assesses a party's opposition to perceived elite dominance in politics.
- **people_centrism**: Indicates emphasis on prioritizing the general public's interest in governance.

To explore these variables, both **summary statistics** and **graphical methods** were used. Measures of center (mean, median) and spread (standard deviation, interquartile range) were computed for each country. For instance, India and the U.S. show relatively high average populism, while Germany exhibits consistently high respect for opponents and gender equality. Outliers—such as exceptionally low gender equality

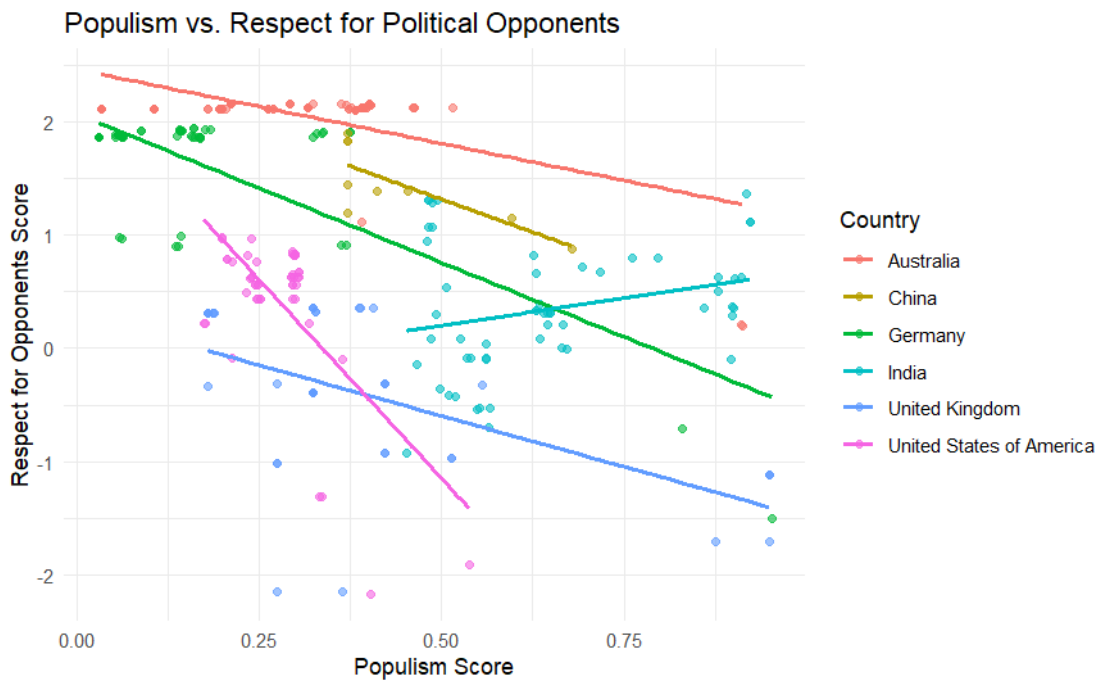
scores in India—were identified and retained for their substantive importance.

Boxplots were created to visualize the variation in key values like gender equality and minority rights across countries. These visuals help detect skewness, outliers, and the general distribution of ideologies. **Scatter plots** were used to examine relationships between variables, such as populism and respect for opponents, or minority rights and political pluralism. These revealed patterns of positive or negative association that informed later inferential analysis.

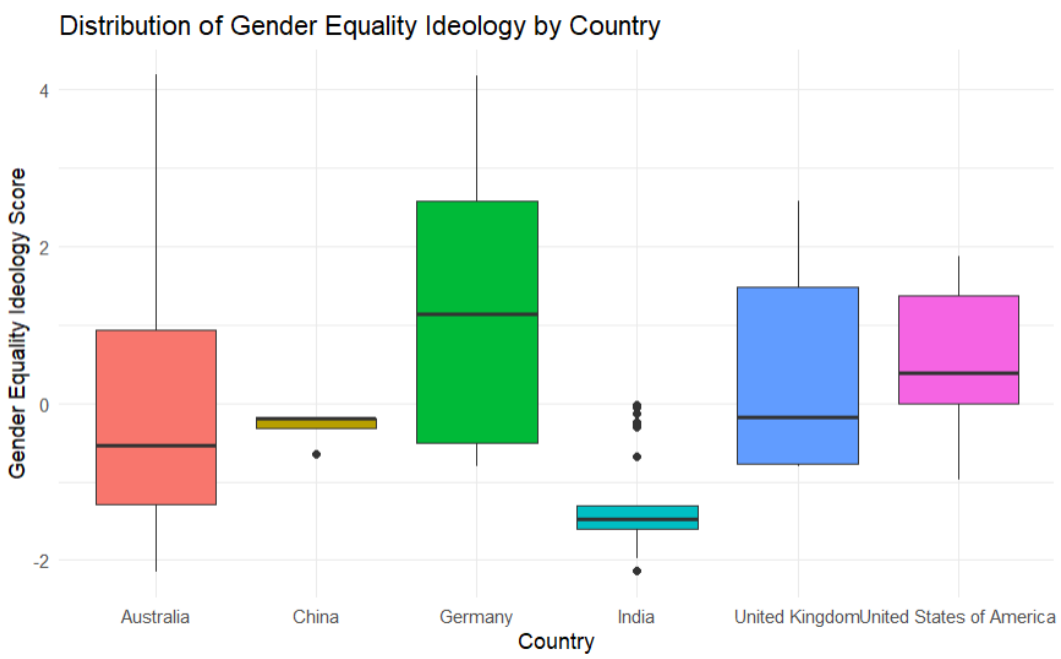
This overview sets the foundation for identifying which ideological traits vary significantly across countries and how these traits might interact with one another in shaping democratic behavior.



This line graph tracks the average populism score of political parties over time for each country. It reveals that populism has fluctuated notably across decades, with India and the U.S. displaying the most variation. Germany and Australia show more stability, whereas China displays generally lower scores. This helps contextualize long-term ideological shifts.

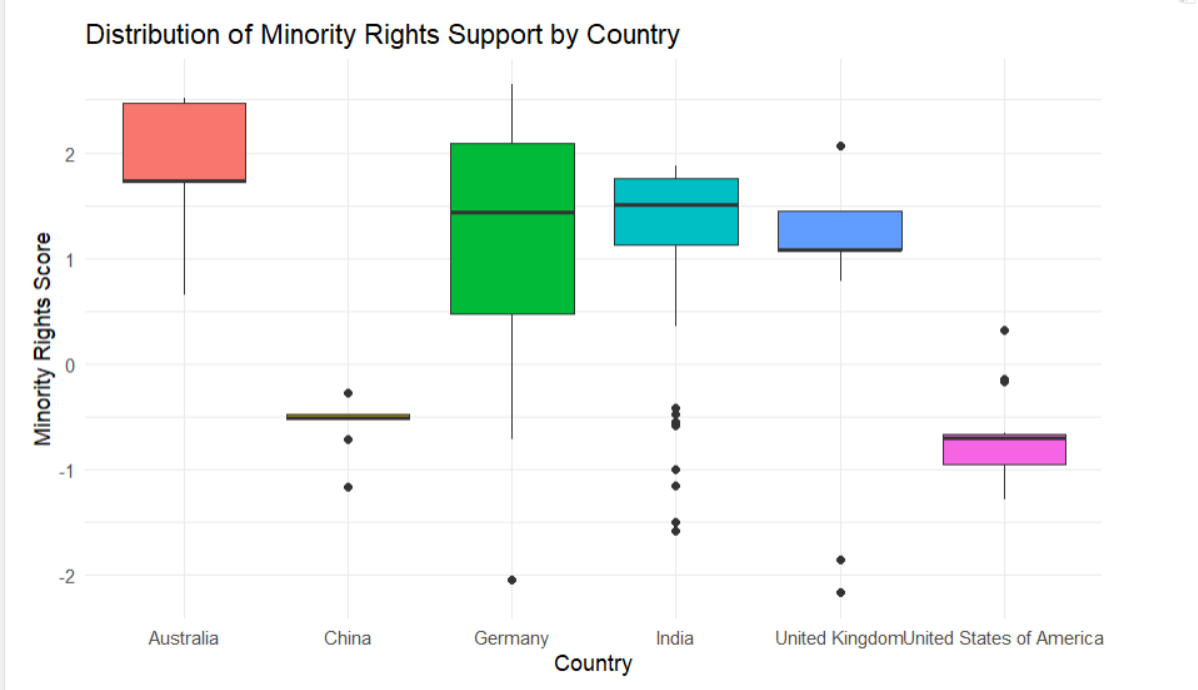


This plot suggests a downward trend: parties with higher populism scores tend to show less respect for political opponents. The clustering of Indian parties in the higher-populism but mid-respect region indicates unique ideological expressions compared to Western democracies.

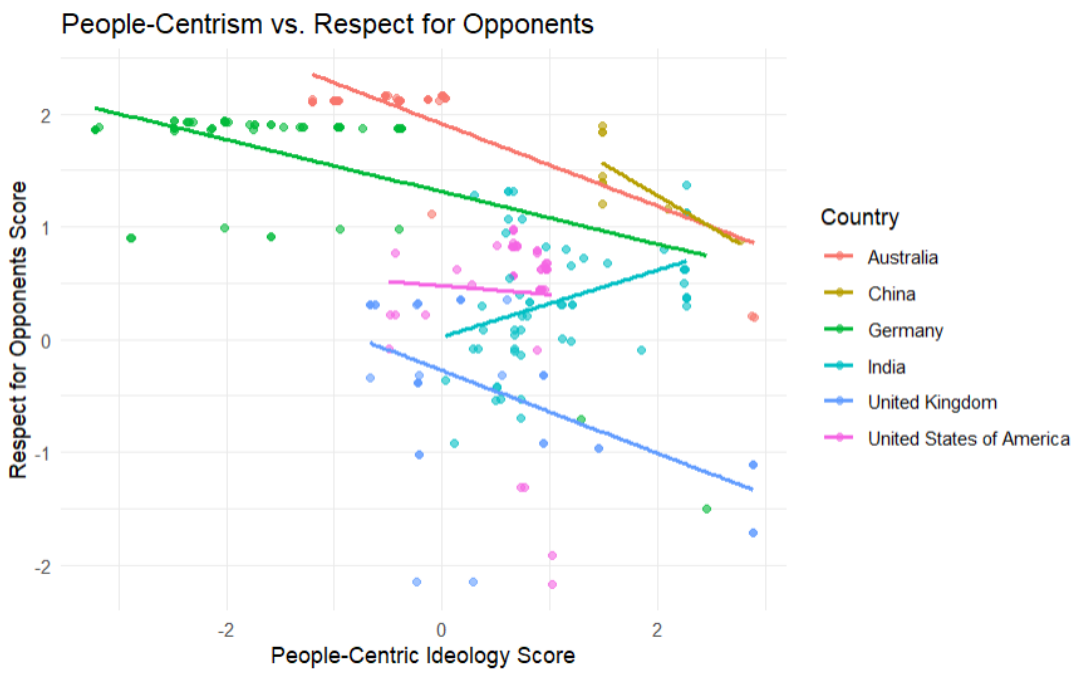


Boxplots indicate that gender equality scores vary considerably across nations. Germany and Australia show tighter distributions around higher

values, while India exhibits a wide spread skewed towards lower equality, highlighting systemic ideological divergence.



This boxplot illustrates how political parties in each country vary in their support for minority rights. Australia and Germany exhibit the highest median levels, suggesting stronger and more consistent backing for minority protections. India and the UK follow with moderate yet varied support, while the United States shows lower median values and a tight interquartile range concentrated below zero. China displays the least support overall, with a notably narrow distribution. These patterns highlight meaningful cross-national differences in how minority inclusion is treated within party ideologies.



This scatterplot examines whether a focus on "the people" within party ideology correlates with democratic respect for opponents. While Australia and China show relatively flat or slightly negative trends, the United Kingdom and Germany exhibit a strong negative association—indicating that as people-centrism increases, tolerance for political opponents tends to decline. India appears more neutral, suggesting a decoupling of these two concepts. The overall pattern raises questions about whether appeals to the public good come at the cost of adversarial respect in some democracies.

Inferential Analysis

To assess ideological trends across countries, several regression models were developed with democratic values as outcome variables and ideological traits as predictors. Both frequentist and Bayesian approaches were applied to validate the robustness of findings.

RQ1: How does the level of populism influence a party's respect for political opponents across different countries?

A linear model with interaction terms revealed a significant negative relationship between populism and respect for opponents ($\beta = -1.31$, $p < 0.001$). This effect varied across countries: while Germany and the U.S. showed steep declines in respect with increasing populism, India showed a modest positive shift. Bayesian estimates reinforced this, with narrow credible intervals and high posterior certainty. These results suggest that populism often coincides with democratic intolerance—except in some contexts like India, where populist discourse may retain a respectful tone.

RQ2: Is there a significant difference in gender equality ideology among political parties across India, the U.S., and Germany?

An ANOVA-like model showed statistically significant differences between the three countries ($F(2, 173) = 62.99$, $p < .001$). Germany had the highest average scores, followed by the U.S., while India lagged significantly ($\beta = -2.5$, $p < .001$). Bayesian modeling confirmed both statistical and practical significance, with India's 90% credible interval not overlapping those of the other countries. These findings underscore gender equity as a deeply polarized ideological dimension.

RQ3: Do countries with higher support for minority rights also exhibit higher political pluralism?

The interaction model showed a positive base relationship ($\beta = 0.11$) between minority rights and political pluralism, although it was not significant at the 0.05 level ($p = .20$). However, country-level differences emerged. For example, China's interaction term was significant ($\beta = 0.77$, $p = .043$), indicating that minority support is more strongly associated with pluralism in this context. Bayesian estimates suggested moderate posterior evidence for positive effects in China and the U.S., with credible intervals excluding zero. Thus, the strength of this link is context-dependent.

RQ4: How does anti-elitism influence people-centric ideology across countries?

This model revealed that anti-elitism is a strong driver of people-centric narratives ($\beta = 0.38$, $p < .001$), particularly in the UK and India, where interaction terms were significant and positive. Germany stood out with a negative interaction ($\beta = -0.31$, $p = .001$), suggesting that anti-elitism in this setting aligns less with grassroots appeal. The Bayesian model mirrored these effects, showing high posterior certainty (Rhat = 1.0) and effective sample sizes above 4,500 for all predictors.

Concluding Paragraph

This analysis underscores the complexity of how political ideologies influence key democratic values such as respect for opponents, gender equality, minority rights, and inclusivity. While democracy is often treated as a universal ideal, the behaviour of political parties across six countries shows substantial variation in how these principles are upheld. Populism, for example, consistently correlates with reduced tolerance toward political opposition—most notably in the United States and Germany—yet India shows a nuanced divergence from this pattern. Similarly, gender equality scores demonstrate a wide gap: Indian parties exhibit notably lower commitment to gender-inclusive ideals when compared to parties in Germany or the United States. The relationship between support for minority rights and political pluralism appears generally positive, but not equally strong across nations, highlighting the influence of local institutional and cultural dynamics. Moreover, people-centric discourse tends to emerge from anti-elitist positioning, especially in countries like the UK, India, and China, suggesting that appeals to 'the people' may serve different purposes depending on political context.

These findings demonstrate that democratic norms are not just institutional but are also shaped by ideology and narrative, and thus vary significantly across borders. For rural community leaders aiming to cultivate informed and engaged citizens, this insight is critical. By equipping individuals with the tools to interpret political messaging critically, education initiatives can strengthen democratic resilience and promote broader participation. Future efforts should expand this work to include more countries, longitudinal shifts in ideology, and the impact of social media and digital platforms. Investing in democratic education, grounded in evidence and free of bias, can help bridge gaps in understanding and ensure all voices are included in shaping the future of governance.

LLM Disclosure

Portions of this final report were developed with assistance from a large language model (LLM), specifically OpenAI's ChatGPT. The LLM was used to support the following aspects of the report:

- **Refining paragraph structure and tone**: Prompts were provided to generate and polish sections such as the introductory paragraph, descriptive overview, inferential analysis interpretations, and the concluding paragraph to ensure clarity and neutrality.
- **Statistical interpretation support**: ChatGPT was prompted with R model outputs (e.g., lm() and stan_glm() summaries) to assist in interpreting both frequentist and Bayesian results in a concise, readable manner.
- **Structural guidance**: Guidance was requested for structuring the report sections in accordance with the assignment rubric and audience expectations (i.e., local community leaders and citizens).

At no point was the LLM used to generate statistical models, clean data, or run analysis in R. All computations and graphs were performed independently using R and verified manually. The LLM served only to assist with narrative development and explanatory writing based on those outputs.

Appendix

This section includes supporting evidence and technical outputs from the statistical analyses conducted in R. All models were estimated using either lm() for frequentist regression or stan_glm() from the rstanarm package for Bayesian analysis. Each result below supports one of the four research questions.

Model Summaries

1. Respect for Opponents ~ Populism * Country

- **Frequentist**: Multiple $R^2 = 0.83$, Adjusted $R^2 = 0.82$, $p < 0.001$
- **Bayesian**: Posterior mean estimate for populism:USA = -2.8 (90% CI: -3.7 to -1.8)
- Interpretation: Populism negatively predicts respect for opponents in most countries; India diverges with a positive association.

2. Gender Equality ~ Country

- **Frequentist**: $R^2 = 0.42$, $p < 0.001$; India significantly lower ($\beta = -2.5$, $p < 0.001$)
- **Bayesian**: Posterior for India = -2.4, SD = 0.2
- Interpretation: Statistically and practically significant differences across countries, with India showing a notably lower average.

3. Political Pluralism ~ Minority Rights * Country

- **Frequentist**: $R^2 = 0.90$, interaction minority_rights:China significant ($p = 0.04$)
- **Bayesian**: Posterior mean for interaction in China = 0.8 (positive correlation)
- Interpretation: Countries differ in how strongly minority rights relate to pluralism, with China showing a stronger-than-average effect.

4. People Centrism ~ Anti-Elitism * Country

- **Frequentist**: $R^2 = 0.76$, all interaction terms for UK, India, Germany significant
- **Bayesian**: Posterior means confirm positive interaction in UK and India, negative in Germany
- Interpretation: Anti-elitist stances are linked to people-centric narratives, but direction and strength vary by national context.

Graphical Evidence

Visuals supporting these findings are included in the knitted R Markdown file. Selected figures include:

- Boxplots of gender equality across countries
- Scatterplots of populism vs. respect
- Interaction plots for minority rights and political pluralism
- Density plots of model residuals

Each plot is explained in the body of the report and demonstrates either between-country variation or key interaction effects.
